CpG depletion is a phenomenon known to be caused by CpG DNA methylation. Although CpG DNA methylation is believed to be a feature of vertebrates and plants [1], we have found that some procaryote genomes such as *M. genitalium* show significantly low CpG frequencies. On the other hand, the genome of *M. pneumoniae*, which is a closely related species to *M. genitalium*, does not show such clear sign of CpG depletion.

In order to discuss possible causes of the bacterial CpG depletion, we conducted computer analyses of frequencies of CpG dinucleotides in twelve complete procaryote genomes, including *M. genitalium* and *M. pneumoniae*.

For all of the complete genome sequences, we first analyzed CpG frequencies in coding and non-coding regions separately. The results of the analysis are shown in Table 1. CpG observed/expected (O/E) values are significantly lower in coding sequences than non-coding sequences in the genomes of *M. genitalium*, *B. burgdorferi* and *M. jannaschii*. In the genome of *M. thermoautotrophicum*, on the other hand, CpG O/E values are about the same in both coding and non-coding sequences.

Comprehensive analysis of mutation patterns of single nucleotide and dinucleotide substitutions has been conducted using homologous sequence pairs of the genomes of of *M. genitalium* and *M. pneumoniae*. These homologous sequences were aligned, and we counted substituted nucleotides and dinucleotides only if six bases directly flanking them (three bases upstream and three bases dowstream) are perfectly conserved. The results are shown in Table 2.

While the point mutations from C (cytosine) in *M. pneumoniae* to T (thymine) in *M. genitalium* are frequent in general, C to T mutations occurred most frequently on the cytocine in the CpG dinucleotide (Table 3).

Table 1: CpG Observed/Expected (O/E) ratio. Expected CpG frequencies are products of C and G single nucleotide frequencies.

species	Whole sequence	Coding sequence	Non coding sequence
Mycoplasma genitalium	**0.39**	**0.37**	**0.54**
Mycoplasma pneumoniae	0.82	0.82	0.83
Escherichia coli	1.16	1.16	1.09
Haemophilus influenzae	1.09	1.09	1.07
Bacillus subtilis	1.04	1.05	0.87
Helicobacter pylori	0.93	0.94	0.84
Borrelia burgdorferi	**0.48**	**0.47**	**0.73**
Synechocystis PCC6803	0.75	0.75	0.68
Aquifex aeolicus	0.87	0.87	0.87
Archaeoglobus fulgidus	0.78	0.77	0.83
Methanococcus jannaschii	**0.32**	**0.27**	**0.67**
Methanobacterium thermoautotrophicum	**0.51**	**0.51**	**0.54**

Table 2: Nucleotide variations in homologous genes of *M. genitalium* and *M. pneumoniae*.

A → T	734	5.67 %
A → G	1003	7.75 %
A → C	401	3.10 %
T → A	922	7.12 %

We therefore conclude that this type of mutations, CpG to TpG/CpA, is the primary force of the CpG depletion in *M. genitalium*. However, since *M. genitalium* does not have a gene homologue to CpG DNA methylase, the cause of the frequent CpG mutation is yet to be known.
